Abstract

The resistance profile of the Klebsiella pneumoniae were left undone despite the increasing prevalence rate of this organism in urinary tract infections (UTI) and its role in antibiotic resistance. The current study was undertaken to know the antibiotic sensitivity profile of Klebsiella pneumoniae, isolated from patients suffering from UTI in our medical college. The study was carried out over a period of 3 years from January 2010 to December 2012. Urine specimens from both outpatients and inpatients of our hospital were processed. Females were more frequently affected than males. ( $P>0.05$ ) The most active antimicrobial agent against K. pneumoniae were piperacillin-tazobactam (72% sensitive), and amikacin (61%). One hundred and fifty two (97.4%) of all the isolates were multi-drug resistant. To conclude, this study stresses the importance of prior knowledge of the sensitivity pattern

Because of the increasing use of antibiotics in the inpatient and outpatient setting, the emergence of resistance to antimicrobial agents has progressed significantly. Traditionally, antibiotic resistance has been a problem only in the management of complicated nosocomial urinary tract infections (UTIs). However, we now are seeing an emergence of antibiotic resistance in ... [\[Show full abstract\]](#)
