## **ABSTRACT**

### **BACKGROUND:**

Anemia is a common concern in geriatric age group (more than 60 years of age) and can have significantly more severe complications than anemia in younger adults. Hence our aim is to evaluate the proportion & morphologic patterns of anemia in geriatric age group.

### **OBJECTIVES:**

To study the proportion and morphological patterns of anemia in elderly patients.

### **METHODS :**

A cross-sectional study of 654 cases of patients of geriatric age group (60 years & above) who have attended geriatric clinic, clinical OPDs & IPDs were studied. A detailed history, complete general physical examination and systemic review of the patients undertaken. Detailed laboratory studies of diagnostic tests were done to fix proportion & patterns of anemia.

### **RESULTS:**

Out of 654 cases, 448 were found to be anemic amounting to 68.5 percentage. Proportion of anemia found to be around 2.1/3. Percentage of anemia in males was 67.6% and in females it was 69.8 percentage. All the patterns of anemia were evident. Normocytic anemia being the commonest pattern constituting 78.1% & the next common was microcytic anemia accounted for 11.6% followed by 6.02% of macrocytic anemia & 4.2% of dimorphic anemia.

### **CONCLUSION:**

Confirming the proportion & patterns of anemia is critical to direct the investigation for profiling the etiology since it is well known that the treatment of anemia goes a long way in improving the overall outcome and quality of life.

**KEY WORDS:** Anemia; elderly; proportion; patterns.

## **LIST OF ABBREVIATIONS USED (In alphabetical order)**

ACD	Anemia of chronic disease
Fe	Iron
Hb	Hemoglobin
IDA	Iron deficiency anemia
MCH	Mean corpuscular hemoglobin
MCHC	Mean corpuscular hemoglobin concentration
MCV	Mean corpuscular volume
NCNC	Normocytic normochromic
NCHC	Normocytic Hypochromic
RBC	Red blood cells
RDW	Red cell distribution width
TIBC	Total iron binding capacity
WBC	White blood cell
WHO	World Health organization

## **INTRODUCTION**

Anemia is a common concern in geriatric age group and can have significantly more severe complications than anemia in younger adults. All the types of anemia are known to occur in this age group & failure to evaluate anemia could lead to delayed diagnosis of potentially treatable conditions<sup>1</sup>.

The decline of hemoglobin and concomitant increased anemia with age is not necessarily, a result of “normal aging”, because anemia is a sign and not a diagnosis. An evaluation is almost always warranted to identify the underlining cause, thus early detection of anemia is an important topic in an older person & should prompt appropriate clinical attention<sup>2</sup>.

Anemia in the elderly can occur in both acute and chronic settings. Multiple pathophysiologic abnormalities in a single elderly patient with anemia are well known. It is essential therefore that the treating physician is aware of the coexistence of anemia in elderly, although the presenting manifestation may be for a different reason. Untreated anemia in geriatric population is associated with greater risk of death, co-morbidities, and impaired functional status. It becomes therefore pertinent to look for severity of anemia, type of anemia, possible etiologies and appropriate correction<sup>3</sup>.

Studies indicate that the prevalence of anemia increases with advancing age and under age 75 years, anemia is more common in females, but over age 75 years it is more common in males.<sup>3</sup> Using World Health Organization criteria for anemia, the prevalence found to range from 8 to 44 percent, with the highest prevalence in men 85 years and older.<sup>1</sup> As reported in the Indian cross-sectional studies prevalence varies between 6% and 30% among males and between 10% and 20% among females. Population based studies in Great Britain have reported prevalence ranges from 5% to 25%.<sup>2,3</sup>

Despite the high prevalence of anemia in the elderly and the increasing size of the geriatric population, only few studies have examined the effects of anemia on elderly patients<sup>2</sup>. There are no data on Indian population as such is available, hence our aim is to document proportion and patterns of anemia as a part of health profile in geriatric age group attending a tertiary care hospital.

## **OBJECTIVES**

- 1) To study the Proportion and Morphological patterns of anemia in geriatric patients attending a tertiary care hospital.

## REVIEW OF LITERATURE

Using World Health Organization criteria, anemia is defined as hemoglobin less than 12 g per dL in female and less than 13 g per dL in male. It is a common clinical problem at all ages, but this is especially true among the geriatric age group (more than or equal to 60 years)<sup>2</sup>. According to epidemiologic data, its prevalence among adults increases sharply after this age group. As a rise in the aging population has been predicted and the prevalence of anemia is expected to rise sharply in the future.<sup>3</sup>

In elderly persons, the etiology of anemia differs sufficiently from younger adults to warrant considering anemia in elderly persons as a distinct entity<sup>4</sup>. The most common causes of anemia in elderly are chronic disease and iron deficiency. Vitamin B12 deficiency, folate deficiency, myelodysplastic syndrome are among other causes.<sup>5,6</sup>

Experienced clinicians recognize the non specific nature of many illnesses like hypertension, diabetes mellitus, and left ventricular dysfunction may produce symptoms similar to that of anemia. Orthopnea, dyspnea at rest and extensive edema are produced only if anemia is severe enough to produce circulatory congestion<sup>6,7</sup>. Careful studies of anemia have indicated that such symptoms may not be associated with anemia until hemoglobin levels lower than 7-8 gm/dl. However there is a paucity of data documenting the prevalence of symptomatology of anemia in elderly patients<sup>8</sup>.

The manifestations such as fatigue, dyspnea on exertion, palpitation, anorexia, faintness, lack of concentration, drowsiness and angina and severity of anemia vary considerably among individuals.<sup>9</sup> It is also associated with mortality and poorer health-related quality of life, regardless of the underlined cause of the low hemoglobin<sup>10</sup>.

It is easy to overlook anemia in the elderly since symptoms of anemia may be attributed to the aging process itself.<sup>11</sup>. Anemia should not be accepted as an inevitable consequence of aging as it may be an important sign that often points to a serious and possibly treatable medical condition<sup>12,13</sup>.

**NHANES-III of WHO study** revealed prevalence of anemia 11% of men and 10.2% of women aged 65 years and older. According to an analysis of the Third National Health And Nutrition Examination Survey (NHANES III), 34% of anemia in older adults was due to folate, B12, or iron deficiency alone or in combination. Twenty percent had anemia of chronic disease (ACD), 12% were associated with renal insufficiency and the remaining 34% were unexplained.<sup>1</sup>

**Chul won choi et al** in his study of anemia in elderly observed that out of 1254 patients 171 were anemic. Out of them 144(11.4%) were women and 27(2.1%) were men. A significant difference in prevalence of anemia was found among the age 60-69 years, 70-79 years and 80 and above years. The most common pattern of anemia in his study was found to be normocytic anemia amounting to 93.5% and 3.5% of them were microcytic, and 3% of them were macrocytic anemias.<sup>2</sup>

**Ramachandra SS et al** has showed in his study that 17.7% of the subjects were anemic based on the cut-offs prescribed by the WHO.<sup>3</sup>

**Celestin Roux et al** reported particularly high prevalences for men in all age groups, ranging from 42.8% in men aged between 70 and 74 years to 59.5% in men 85 years<sup>4</sup>.

**Salive et al** examined the association between anemia in the elderly and morbidity and Hospitalization<sup>5</sup>.

**Hee-seon Kim et al** in his study observed that out of 562 subjects, 70 subjects (25 men and 45 women) were anemic. The prevalence rate of anemia was 12.3%. The prevalence of anemia was the lowest among age group of 60-69 years followed by age group of 70-79 and the highest among the age group over 80 years. The most common pattern of anemia in his study was found to be normocytic anemia amounting to 90.2% and 0.9% and 8.9% were microcytic and macrocytic anemias respectively.<sup>6</sup>

**Jack M. Guralnik et al** revealed that overall, 11.0% of men and 10.2% of women 65 years and older and living in the community are anemic according to WHO criteria.<sup>7</sup>

**Stefano Muzzarelli** has shown that anemia proved to be an independent predictor of death and major clinical adverse events among elderly patients with stable symptomatic coronary artery disease.<sup>8</sup>

**Artz AS et al** showed that 14% to 50% of anemic elderly had no obvious underlying cause.<sup>9</sup>

**Lesourd 2004** studies showing that chronic under nutrition in older persons is associated with a relative down regulated immune response and low lymphocyte counts, which were the two main correlates of unexplained anaemia.<sup>10</sup>

**Nissensohn et al** study revealed that prevalence of anemia in general elderly population was 7.5% for males & 20% for females<sup>11</sup>.

**Elis et al** have shown that most common anemia in elderly is normocytic normochromic type.<sup>12</sup>

**Gerbrand J.Izaks et al** have shown that a low hemoglobin concentration at age signifies disease<sup>15</sup>.

**Milman N et al** has shown that about 5.8% of the total anemia population had myelodysplastic syndrome. And 17.2 % of the patients had unexplained anemia<sup>16</sup>.

**Carmel et al** has shown that the highest rates of anemia occur in hospitalized Populations<sup>17</sup>.

**Kikuchi et al** studied the relation between anemia and mortality in the elderly<sup>19</sup>.

**Amit Bhasin et al** study shows that most common pattern of anemia was normocytic & commonest cause of anemia was anemia of chronic diseases<sup>44</sup>.

## **Anemia**

Anemia, is not a diagnosis in itself, but is an objective sign for presence of disease.

Anemia is defined as a condition in which the concentration of hemoglobin in peripheral blood is below the level that is normal for the level for that age and sex of an individual<sup>13</sup>.

The normal limit of hemoglobin concentration varies among definitions established by different organizations. World health organization criteria for anemia are hemoglobin less than 12 g/dl in women and less than 13 g/dl in men. This definition is the most frequently used<sup>14</sup>.

### **EVALUATION OF ANEMIA IN ELDERLY**

Anemia in the elderly is evaluated in a manner similar to that in younger adults, including an assessment for signs of gastrointestinal blood loss, hemolysis, nutritional deficiencies, malignancy, chronic infection (such as subacute endocarditis), renal or hepatic disease, and other chronic disease<sup>15</sup>. In patients without evidence of an underlying disease, the initial laboratory evaluation should include a complete blood count, red blood cell indices, a reticulocyte count and peripheral blood smear<sup>16,17</sup>.

Anemia algorithms used for evaluation of younger adults are based on the mean corpuscular volume. Such algorithms may be less helpful in the elderly because the classic changes in erythrocyte size do not often accompany anemia in this age group<sup>18</sup>. In most elderly patients with anemia, red cell indices disclose normocytic, normochromic

anemia. It also should be remembered that the cause of anemia is not always found. A bone marrow examination is rarely necessary in initial evaluation of anemia in older patients<sup>19,20</sup>.

The vast majority of uncomplicated anemia can be diagnosed without a bone marrow examination. However the procedure should be performed when the anemia is accompanied by abnormalities in WBC or platelets or when marrow infiltration is suspected. The examination is no more dangerous or painful in older people than in younger people<sup>21,22</sup>.

## **ETIOPATHOGENESIS OF ANEMIA IN ELDERLY.**

**Table 1- Common causes of Anemia in the Elderly<sup>23</sup>**

<b>Cause of Anemia</b>	<b>Percentage of Cases (%)</b>
Anemia of chronic disease (ACD)	30 to 45
Iron deficiency	15 to 30
Post hemorrhagic	5 to 10
Vitamin B12 and folate deficiency	5 to 10
Chronic leukemia or lymphoma	5
Myelodysplastic syndrome	5
No identifiable cause	15 to 25

## **NORMOCYTIC ANEMIAS**

### **ANEMIA OF CHRONIC DISEASE**

Anemia of chronic disease, also called anemia of chronic disorders, is the most common form of anemia in the elderly<sup>25,26</sup>. Numerous diseases are associated with anemia of chronic disease, but in many cases an underlying disease is not identified. The hematologic abnormality in anemia of chronic disease is an impaired ability to use the iron stored in the reticuloendothelial system. Erythrocytes are usually normochromic and normocytic, but about one third of patients with anemia of chronic disease have microcytosis<sup>27,28</sup>.

### **Anemia of renal disease**

In renal insufficiency, a normochromic anemia develops which is very similar to Anemia of chronic disease (ACD). In this condition there is a deficiency of erythropoietin production, and there is evidence that the administration of erythropoietin, when the anemia is severe, can partially improve the condition<sup>29,30</sup>.

### **Anemia of endocrine disorders**

Endocrine disorders that commonly produce anemia are hypothyroidism, hypopituitarism, and adrenal insufficiency. In all three diseases the anemia is normocytic and normochromic but may be macrocytic<sup>31</sup>.

### **Anemia of liver disease**

In liver diseases, a normocytic or macrocytic anemia develops. There are many causes of anemia in liver disease, including bleeding, iron deficiency, folate deficiency, hypersplenism, and sideroblastic anemia<sup>31,32</sup>. In liver disease, however, serum iron is increased and there is an increase in transferring saturation. Serum ferritin is also increased and often reflects total body iron overload<sup>33</sup>.

### **Anemia of collagen vascular diseases**

Anemia of chronic disease appears in collagen vascular diseases such as rheumatoid arthritis, polyarteritis, dermatomyositis, systemic lupus erythematosus, and temporal arteritis (including polymyalgia rheumatica)<sup>31,34</sup>.

### **“Unexplained anemia” of elderly people**

A mild, normocytic normochromic anemia with a hemoglobin concentration usually between 11 and 12 g/dL has been reported in people over the age of 70. This anemia cannot be accounted for any underlying disease or deficiency, and the bone marrow does not contain ringed sideroblasts. This unexplained anemia is said to account for over 30 percent of the anemias in this age group<sup>29,35</sup>.

### **Anemia of cancer in elderly**

The incidence and prevalence of cancers increases with age. Anemia is present in more than 60% of cancer patients and the risk of anemia is higher with more advanced stages of cancer. The most common mechanisms of anemia in cancer patients are chronic inflammation and myelotoxic treatment such as chemotherapy and radiation therapy<sup>36,37</sup>.

## **MICROCYTIC ANEMIA**

### **Iron deficiency anemia**

Iron deficiency anemia, the second most common cause of anemia in the elderly, usually results from chronic gastrointestinal blood loss caused by nonsteroidal anti-inflammatory drug induced gastritis, ulcer, colon cancer, diverticulum or angiodyplasia<sup>38</sup>. Chronic blood loss from genitourinary tract cancer, chronic hemoptysis and bleeding disorders may result in iron deficiency but are much less common causes. Older persons may become iron deficient because of inadequate intake or inadequate absorption of iron<sup>39</sup>.

### **Other Causes of Microcytic Anemia :-**

Anemias caused by abnormal hemoglobin (e.g. sickle cell anemia) are usually not first diagnosed in old age. Thalassemia minor, since it is asymptomatic, may first be found in old age. The anemia of chronic disease may be microcytic, but it is more commonly normocytic. Sideroblastic anemia may be microcytic, normocytic, or even macrocytic<sup>40</sup>.

## **MACROCYTIC ANEMIA**

Macrocytic anemia is described as an anemia in which the MCV is greater than 100 fl. MCV increases slightly with increasing age but usually not enough to produce significant macrocytosis. Relatively few disorders routinely result in macrocytic anemia. The two common disorders that produce macrocytosis are megaloblastic anemias due to either vitamin B12 or folate deficiency<sup>26,40</sup>.

## **MYELODYSPLASTIC SYNDROME**

Myelodysplastic syndrome is a relatively uncommon cause of anemia, but is a more common cause in the elderly than in younger patients<sup>41</sup>. The syndrome is characterized by a defect in the development of one of the marrow cell lines, limiting the release of functioning cells. Anemia results when the red cell lines are affected. Myelodysplastic syndrome should be a diagnostic consideration when white cell or platelet abnormalities accompany the anemia. The diagnosis of this syndrome is usually made by bone marrow aspiration & biopsy<sup>42,43</sup>.

## **MATERIALS & METHODS**

### **Source of Data**

Patients of geriatric age group [60yrs and above]<sup>6</sup> who have attended geriatric clinic & clinical OPD's & IPD's in BLDE University Shri B.M.Patil Medical College, Hospital and Research Centre, Bijapur, Karnataka, India during the period between November 2010 to April 2012.

### **Method of Collection of Data**

A cross-sectional study of 654 patients satisfying the inclusion and exclusion criteria, managed by Departments of pathology, BLDE University Shri B.M. Patil Medical College, Hospital & Research Centre, Bijapur Karnataka were studied. Detailed history of included patients were elicited. A complete general physical examination and systemic review of the patients were undertaken.

### **The following investigations have been carried out for all the patients:**

Hemoglobin (g/dl)

Total leukocyte count & differential leukocyte count

Platelet count.

Erythrocyte sedimentation rate [ESR],

Packed cell volume [PCV],

RBCs indices -: MCV, MCHC, MCH & RDW.

Peripheral smear study

Reticulocyte count.(if indicated)

Bone marrow aspiration study was carried out wherever necessary.

Additional investigations as indicated for detection of underlying cause [upper GI endoscopy and colonoscopy, tissue biopsy, imaging-CT/MRI] were carried out wherever necessary.

#### **INCLUSION CRITERIA:**

All the geriatric patients of either sex who have attended geriatric clinic, clinical OPD's & admitted to IPD's were included.

#### **EXCLUSION CRITERIA:**

Patients with a history of recent blood transfusion

Patients who have undergone major surgical procedure in the past 3 months.

Patients who were on haematinics , Vitamin B12 or folic acid.

#### **Study Design**

Observational study (Cross Sectional Study)

#### **Sample Size:**

With prevalence rate of Anemia among elderly is 33% (Average prevalence of 6-30% among male & 10-20% among female)<sup>2</sup>, and considering 99% level of confidence and 20% allowable error,

Using statistical formula

$$n = \frac{(2.56)^2 p (1-p)}{L^2}$$

$$L^2$$

p = Prevalance rate of anemia among elderly people =33%

L = Allowable error =20%

The calculated sample size was 333.

But 654 prospective cases were studied in particular duration.

As per **WHO criteria**, anemia is defined as hemoglobin count < 13g/dl in males and < 12 g/dl in females<sup>1</sup>.

**Patterns of anemia** are classified based on RBC indices & further correlated by peripheral smear. Microcytic anemia was defined as MCV below 80 fl, normocytic as MCV between 80 and 100 fl and macrocytic anemia by an MCV above 100 fl. Dimorphic anemia are suspected when RDW is more than its normal range(11-15%) & then correlated by peripheral smear.<sup>44</sup>

**Table – 2. Severity<sup>24</sup>** of anemia graded as mild, moderate & severe

Severity	World Health Organization
Grade 1 (Mild)	10-11.9 gm / dl
Grade 2 (Moderate)	7.1-9.9 gm / dl
Grade 3 (Severe)	<7 gm / dl

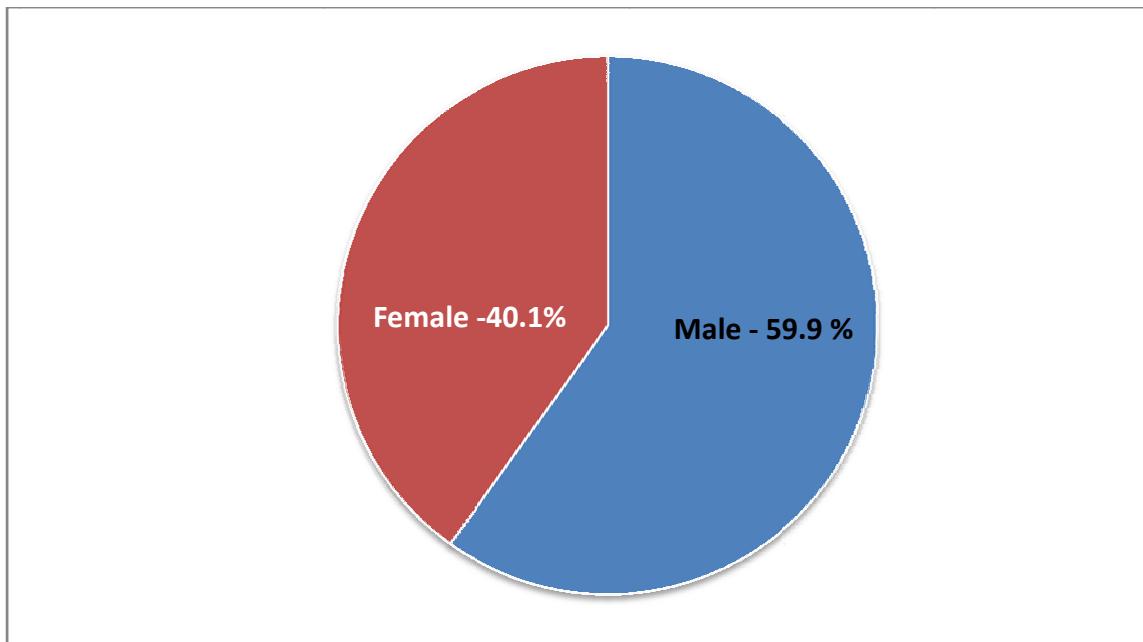

## **RESULTS**

### **PART 1: BASE LINE DATA**

**Table: 3 – Distribution of study subjects according to sex**

<b>Gender</b>	<b>Number of subjects</b>	<b>Percentage</b>
Male	392	59.9
Female	262	40.1
Total	654	100

<b>Age in years</b>	<b>Total</b>	<b>Sex</b>	
		Male	Female
60-69	385	226	159
70-79	201	125	76
>80	68	41	27
Total	654	392	262

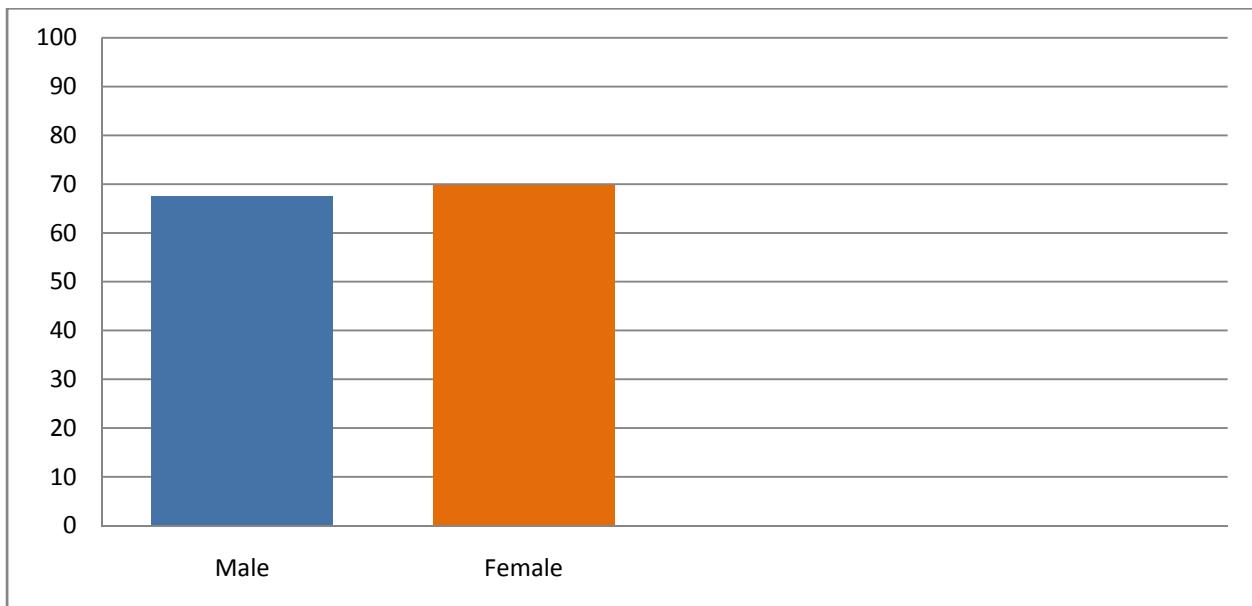

## **PART 2: RESULTS ON PROPORTION OF ANEMIA AMONG STUDY SUBJECTS**

In this study, the Proportion of anemia found was 2.1/3 i.e. 68.5% in BLDEU Shri B.M.Patil Medical College Hospital & RC, Bijapur, Karnataka. Percentage of anemia in males was 67.6% and in females it was 69.8 percentages.

**Table: 6- Percentage of anemia in study subjects according to sex**

Sex	Anemia		Total	Percentage
	Yes	No		
Males	265	127	392	67.6
Females	183	79	262	69.8
Total	448	206	654	68.5

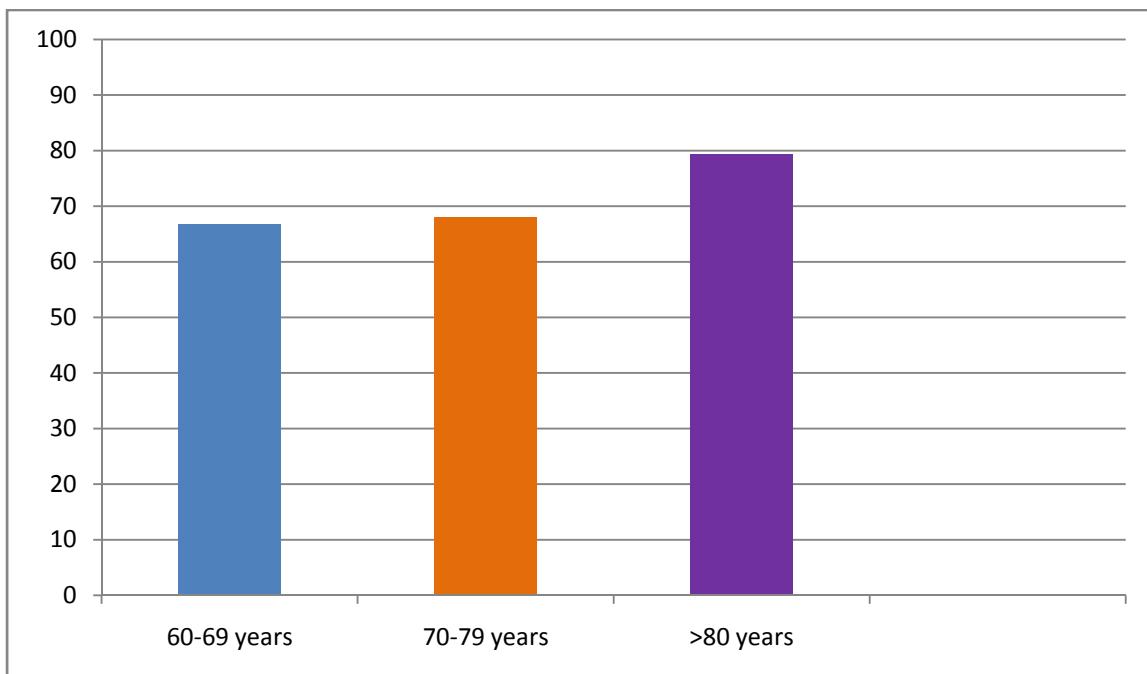

**Figure: 3- Bar diagram showing percentage of anemia in study subjects according to sex**

**Table: 7- Percentage of anemia in study subjects according to age**

Age in years	Anemia		Total	Percentage
	Yes	No		
60-69	257	128	385	66.7
70-79	137	64	201	68.1
>80	54	14	68	79.4
Total	448	206	654	68.5

**Figure 4 – Bar diagram showing Percentage of anemia in study subjects according to age**

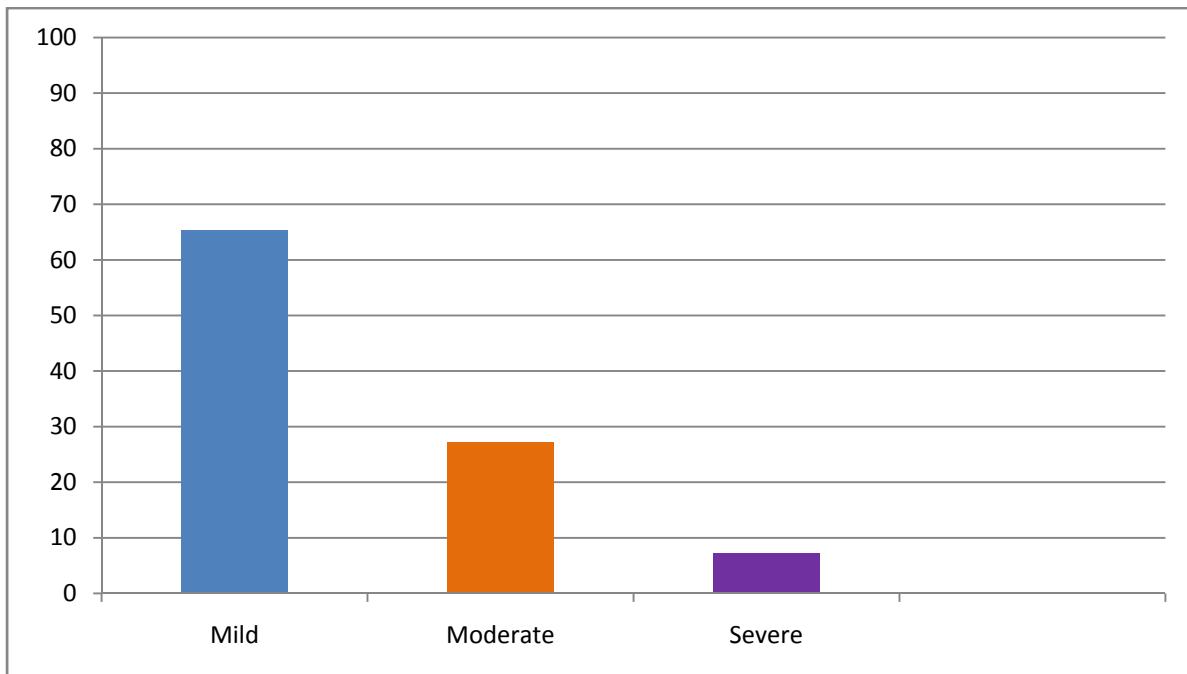

**Table 8 – Distribution of anemic study subjects according to severity.**

Sex	Mild	Moderate	Severe
Male (265 )	180	60	25 (9.3%)
Female (180)	113	62	8 (4.4%)
Total (448)	293	122	33
Percentages	65.4	27.3	7.3

Lowest hemoglobin found was 1.8g/dl in males & 3.9g/dl in females.

**Figure 5 – Bar diagram showing distribution of anemic study subjects according to severity.**

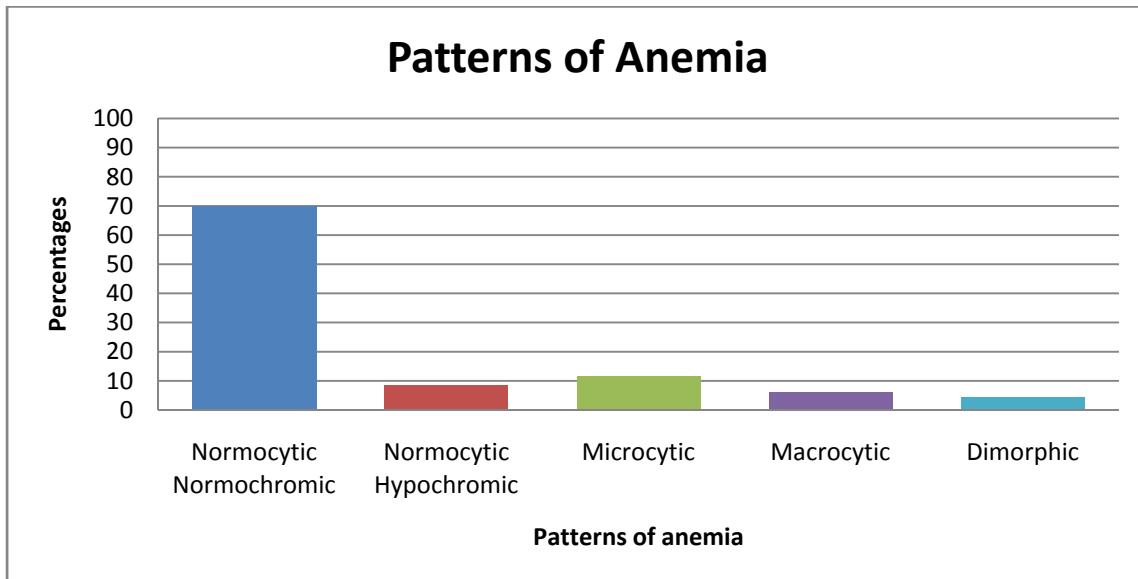

### **PART 3: RESULTS ON PATTERNS OF ANEMIA**

For the study of patterns of anemia we took all 448 anemic patients among the study subjects.

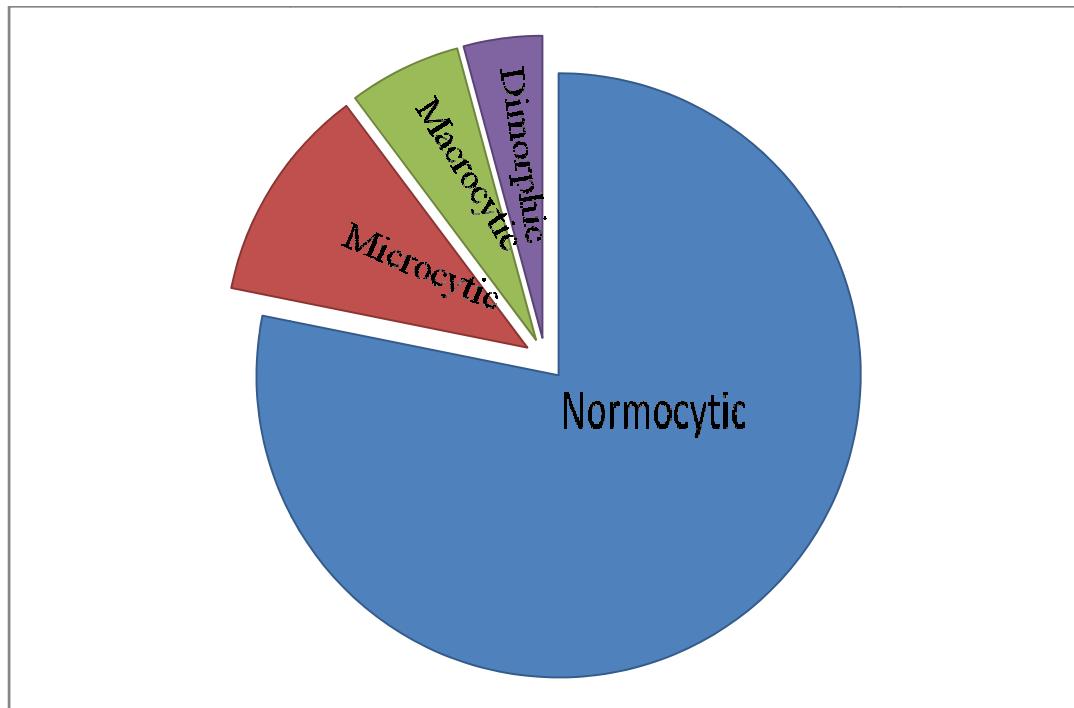

**Table: 9- Distribution of the anemic subjects according to patterns of anemia**

Patterns of anemia	Frequency	Percentage
Normocytic normochromic	313	69.8
Normocytic hypochromic	37	8.25
Microcytic hypochromic	52	11.6
Macrocytic	27	6.02
Dimorphic	19	4.24
Total	448	100

**Figure: 6 – Bar diagram showing distribution of anemic subjects according to patterns of anemia**

**Figure: 7 – Pie chart showing distribution of the study subjects according to patterns of anemia**

## **NORMOCYTIC ANEMIA**

**Table: 10 -Distribution of Normocytic anemia according to sex**

<b>Gender</b>	<b>Number</b>	<b>Percentage</b>
Males	207	59.4
Females	143	40.6
Total	350	100

350 patients of the total 448 anemic patients had underlying normocytic anemia. Out of the 350 patients, 207 were males and 143 were females.

## **MICROCYTIC ANEMIA**

**Table: 11- Distribution of patients of microcytic anemia according to sex**

<b>Gender</b>	<b>Number</b>	<b>Percentage</b>
Males	31	59.6
Females	21	40.4
Total	52	100

52 patients of the total 448 patients had underlying microcytic anemia. Out of the 52 Patients, 31 were males and 21 were females.

## **MACROCYTIC**

**Table: 12- Distribution of macrocytic anemia according to sex**

<b>Gender</b>	<b>Number</b>	<b>Percentage</b>
Male	15	55.5
Female	12	44.5
Total	27	100

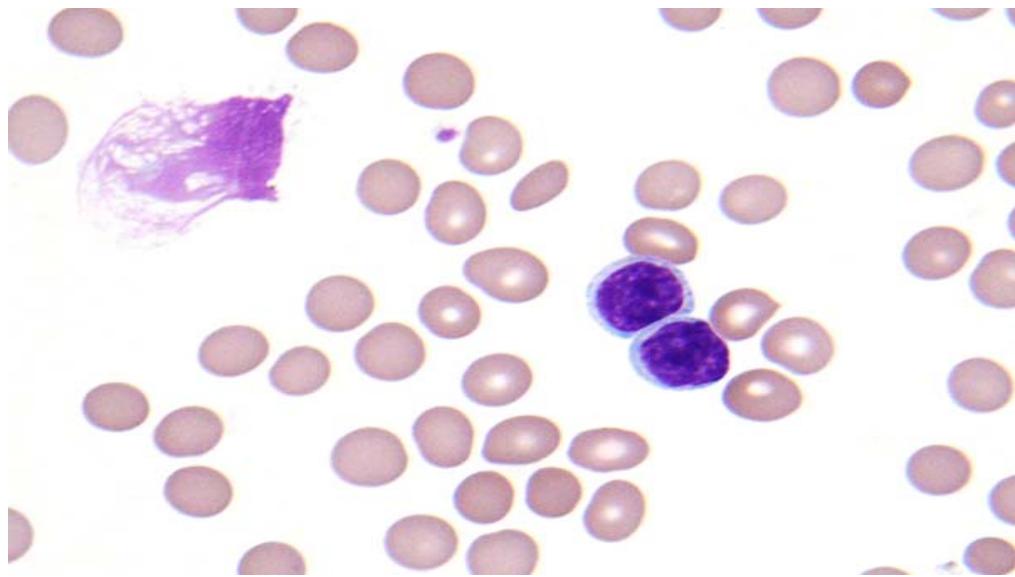

27 patients of the total of 448 anemic patients had underlying macrocytic anemia. Out of the 27 patients, 15 were males and 12 were females.

## **DIMORPHIC ANEMIA**

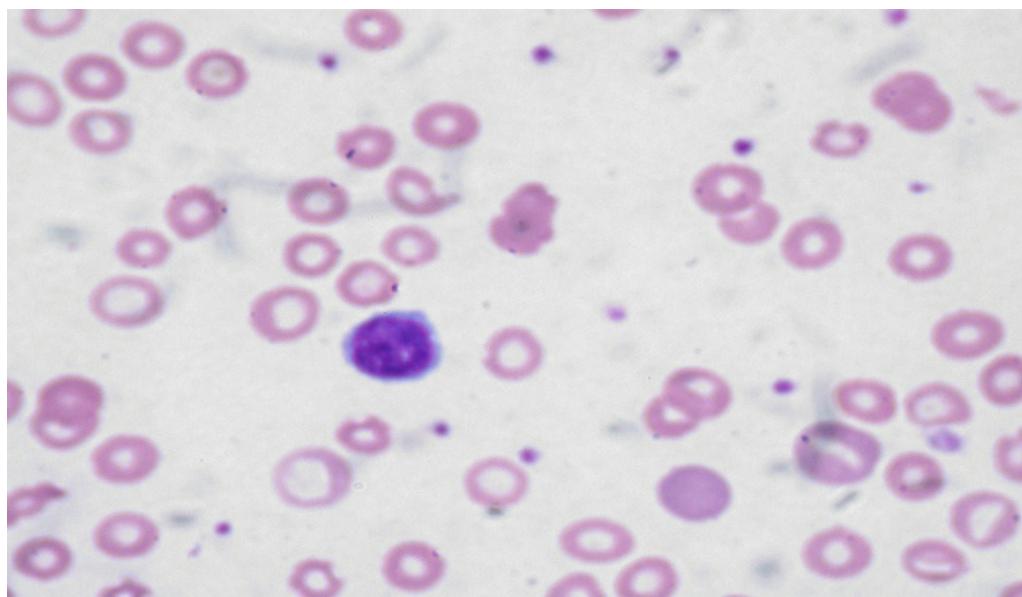

**Table: 13- Distribution of dimorphic anemia according to sex**

<b>Gender</b>	<b>Number</b>	<b>Percentage</b>
Male	12	63.2
Female	07	36.8
Total	19	100

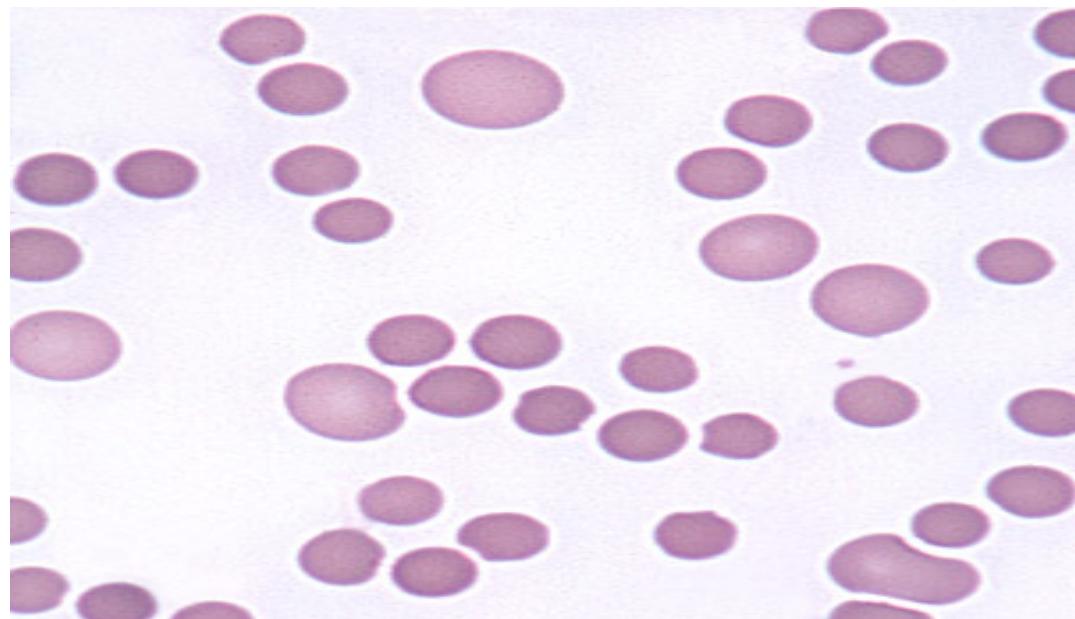

19 patients of the total of 448 anemic patients had underlying dimorphic anemia. Out of the 19 patients, 12 were males and 07 were females.

## **DISCUSSION**

Aging is associated with increased incidence and prevalence of anemia, that is associated with a number of adverse health outcomes. These include functional dependence, increased risk of therapeutic complications, falls, dementia and death. In approximately 30% of cases, anemia in older individuals is due to either relative or absolute erythropoietin deficiency. Absolute erythropoietin deficiency may be primary or secondary to declining renal function. Relative erythropoietin deficiency is due to an age-related pro-inflammatory status that reduces the sensitivity of erythropoietic precursors to erythropoietin<sup>2,8</sup>.

Despite this condition of erythropoietin deficiency, the management of anemia of aging with erythropoiesis stimulating factors (ESF) is controversial, unless the anemia is due to renal insufficiency<sup>16</sup>. The main concern related to this treatment arises from eight studies of ESFs in cancer, suggesting that ESFs may reduce patient survival, in addition to increasing the risk of deep vein thrombosis<sup>17,18</sup>.

Anemia in elderly is a frequent, underappreciated and potentially morbid condition. However, public health improvement for the anemic elderly involves a complex set of scientific, clinical and societal issues<sup>32</sup>. Anemia is associated with symptoms ranging from weakness and fatigue, palpitations, depression and in severe cases can lead to

congestive cardiac failure. Age related disability and loss in physical function are growing public health priorities. Loss in physical function threatens the independence and quality of life of older adults and has substantial social and economic effects<sup>33</sup>.

Although it was previously believed that decline in hemoglobin level might be a normal consequence of aging, evidence has accumulated that anemia does reflect poor health and increased vulnerability to adverse outcome in older persons. The decline of hemoglobin and concomitant increased anemia with age is not necessarily a result of "normal aging" so the detection of anemia in an older person should prompt appropriate clinical attention<sup>19,20</sup>.

In our study percentage of anemia calculated was 68.5% while according to **WHO report (2000)**<sup>14</sup>, prevalence of anemia in older individuals is about 50% in developed countries and 12% in developing countries.

In Present study, percentage of anemia in male was 67.6% & in females was 69.8%. While **NHANES-III of WHO**<sup>45</sup> study revealed prevalence of anemia in 11% of men and 10.2% of women aged 65 years and older. However ours study was a hospital based as compared to this study which was population based.

In our study percentage of anemia in males (67.6%) was less as compared to females (69.8%) in contrast to **Guralink J.M et al**<sup>20</sup> whose study showed that 11.0% of men and 10.2% of women of 60 years and above are anemic.

In present study percentage of anemia was lowest among age group of 60-69 years (66.7%) followed by 70-79 years (68.1%) age group and the highest among the age group over 80 years (79.4%). Most common pattern in present study was found to be Normocytic anemia accounting for 78.1%. **Hee-seon Kim et al**<sup>6</sup> study correlates closely with present study.

Our study revealed that proportion of anemia increases with age which is confirmed by **Celestin Roux et al**<sup>4</sup> study.

Present study shows that most common anemia in elderly is normocytic normochromic type (69.8%). In order of type of anemia **Elis et al**<sup>12</sup> study corroborates with present study.

In present study percentage of anemia was 68.5%, of which Normocytic being the commonest constituting 78.1% followed by microcytic 11.6%, macrocytic 6.02 & dimorphic 4.2%. **Ania et al**<sup>1</sup> diagnosed anemia in 36% of males, being normocytic in 83%, microcytic in 14% , and macrocytic in 3%, as compared to 44% of women ,which

was microcytic in 16%, normocytic in 80%, and macrocytic in 4% of cases. Hence our study closely tallies with this study, depicting normocytic anemia being the most common in both males and females.

## **SUMMARY**

Patients of both the sexes, above the age of 60 years were included between the period of November 2010 to April 2012. Percentage of anemia in geriatric age group calculated was 68.5%, accounting to proportion around 2.1/3 of study subjects. In females it was more (69.8%) than males (67.6%). Percentage of anemia increased with age, i.e. highest in > 80 years age group (79.4%) followed by 70-79 years age group (68.1%) & lowest in 60-69 years age group (66.7%).

All the types of anemia were evident. Normocytic being the commonest, constituting 78.1% followed by microcytic 11.6%, macrocytic 6.02 & dimorphic 4.2% in either sex & in different age groups of study subject.

Majority of Anemia was found to be mild (65.4%) followed by moderate ( 27.3%) & severe (7.3%) . Severe anemia was found to be more in males (9.3%) as compare to females (4.4%) & severity of anemia increased with the increasing age.

Fatigue was the most common symptom encountered in the anemic population.

## **CONCLUSION**

Anemia is a significant common association in the elderly and its proportion in the present study was found to be 2.1/3, which is high may be because study was done in tertiary care hospital. Proportion of anemia found to be slightly increased in females as compared to males. Most common patterns of anemia found was normocytic followed by microcytic, macrocytic & dimorphic in either sex & different age groups. Majority of the anemia was mild in either sex & severity increased with increasing age groups.

Confirming the patterns of anemia is critical to direct the investigation for profiling the etiology since it is well known that the treatment of anemia goes a long way in improving the overall outcome and quality of life.

Hence, it is necessary to evaluate the anemia status in all elderly patients as a part of health profile in geriatric age group.

## **ANNEXURE II**

### **PROCEDURE :- Leishman's Stain**

#### **REAGENTS:-**

Leishman powder - 0.15gm

Methyl Alcohol (acetone free ) – 100ml.

**Leishman powder :-** Equal quantities of polychromed Methylene Blue (1 %) and Eosin B (0.1%)

#### **PROCEDURE :-**

- 1) Air dried film was flooded with leishman's stain for 2 minutes.
- 2) Double the volume of buffer water was added for 10 minutes.
- 3) The stain was washed off with distilled water until it acquired a pinkish tinge.
- 4) After drying, the back of the slide was wiped clean.
- 5) The slide was mounted with D.P.X
